Humans and climate change

Human populations are at the center of climate change research. On the one hand, human activities contribute to climate change. On the other hand, changes in the climate system affect human wellbeing and livelihoods. Both the contribution to and the impact of global warming is not distributed equally across the planet. Rather, different people in different places contribute and suffer to different degrees, depending on their characteristics and their level of affluence. Climate risks are the outcome of differential exposure and vulnerability to hazards. Understanding the reciprocal relationships between human populations and climate change and how they will evolve in the future, thus, is crucial for policy design and planning, both in the area of mitigation and adaptation.

Vulnerability and adaptation

Wittgenstein Centre research comprises two key elements. First, we assess the direction and the extent to which climate change affects human populations with a focus on demographically differentiated vulnerability. Using advanced statistical methods, we produce the empirical evidence on how climate variability and extremes affect subgroups of populations depending on their sociodemographic characteristics, as well as location-specific aspects that affect their livelihoods. Different demographic outcomes are considered, including impacts on migration, health and well-being, and union formation and fertility. Second, we apply demographic techniques, in particular, multidimensional cohort-component population projections to predict future vulnerability and adaptive capacity given changes in population composition and distribution under different scenarios. Such predictions of future vulnerability are of high societal relevance because they allow for more specific interventions to tackle foreseeable future threats.

Regional differences

The impact of climate change is already being felt in all regions of the world. However, the impact is not distributed evenly. The areas where the population is already vulnerable, e.g. because of civil strife, high levels of poverty, and poor services and infrastructure will have lower capacity to respond to, cope with and adapt to climate change. Rural areas that depend heavily on rain-fed agriculture will be vulnerable to food insecurity, while urban areas are vulnerable to heat extremes. Even in a high-income country like Austria, certain subgroups of the population, particularly the elderly, but also children, minorities and marginalized groups can be more vulnerable to climate risks than others due to their higher susceptibility to certain climatic hazards and lower adaptive capacity.

Disaster displacement in Africa and the Middle East, South and Eastern Asia, and Latin America and the Caribbean. 2019

The role of education

The climate-related research carried out at Wittgenstein Centre over the past couple of years has consistently shown that formal education matters for both climate change mitigation and adaptation. In particular, we show that providing at least secondary level of education universally can substantially reduce disaster vulnerability. At the same time, education enhances adaptive capacity through changing risk perception, increasing awareness, and improving socioeconomic resources necessary to implement adaptation and responses to change. Further investments into both climate mitigation and adaptation are needed. In particular, a focus should be placed on those population groups that are characterized by a high vulnerability, making them more susceptible to the consequences of climate change. Together with demographic factors, social inequality and poverty are important vulnerability drivers. Policy can provide effective support by strengthening adaptive capacities and by building resilience, among others through increased education.

Uncertain future

Up until now, we have analyzed the impact of climate variability and extremes that occurred in a 1.2°C world (global mean near-surface temperature 1.2°C warmer than the pre-industrial level). Even under these comparatively moderate levels of warming, we have already observed the effects on human health, wellbeing and livelihoods. For instance, there is evidence that migration increases in response to adverse climatic conditions. However, these effects are highly contextual and in some contexts, migration has also been shown to decline, as climate change deprives people of the resources necessary to afford to migrate. Nonetheless, there are many things that we still do not know about the future, when much more extreme changes are likely. Given the current trends in greenhouse gas emissions, the global average temperature is on the course of rising by 3°C compared to pre-industrial levels by the end of the century.

Projections of future climate impact typically consider only biophysical changes but neglect future societal changes. The key contribution of our work is to point out that the climate of the future will not match the societies of today i.e. emphasizing that future societal and demographic changes need to be accounted for when predicting future societies’ vulnerability to climate change. We provide critical information for policy makers to improve decision-making related to tackling the impacts of future socioeconomic and demographic trajectories. We help identify specific population subgroups, as well as geographical vulnerability hotspots where interventions are most urgent given existing resource constraints.
